Biol 4220 @ WUSTL

Course: Practical Bioinformatics (BIOL 4220)
Instructor: Michael Landis
Email: michael.landis@wustl.edu

Practical bioinformatics

Practice foundational computing skills
for everyday biological research

We all have different backgrounds,
research interests, goals, etc.

Practical bioinformatics

Broad goals:

- Learn new computer skills for biological data analysis
- Translate research ideas into code
- Solve problems independently
- Communicate in technical terms

Practical bioinformatics

Specific skills we'll develop:

- Write and debug programs
- Build your own analysis pipeline
- Test hypotheses with pipelines
- Make reproducible research
- Communicate research findings

Instructors

Instructor

chayh@wustl.edu

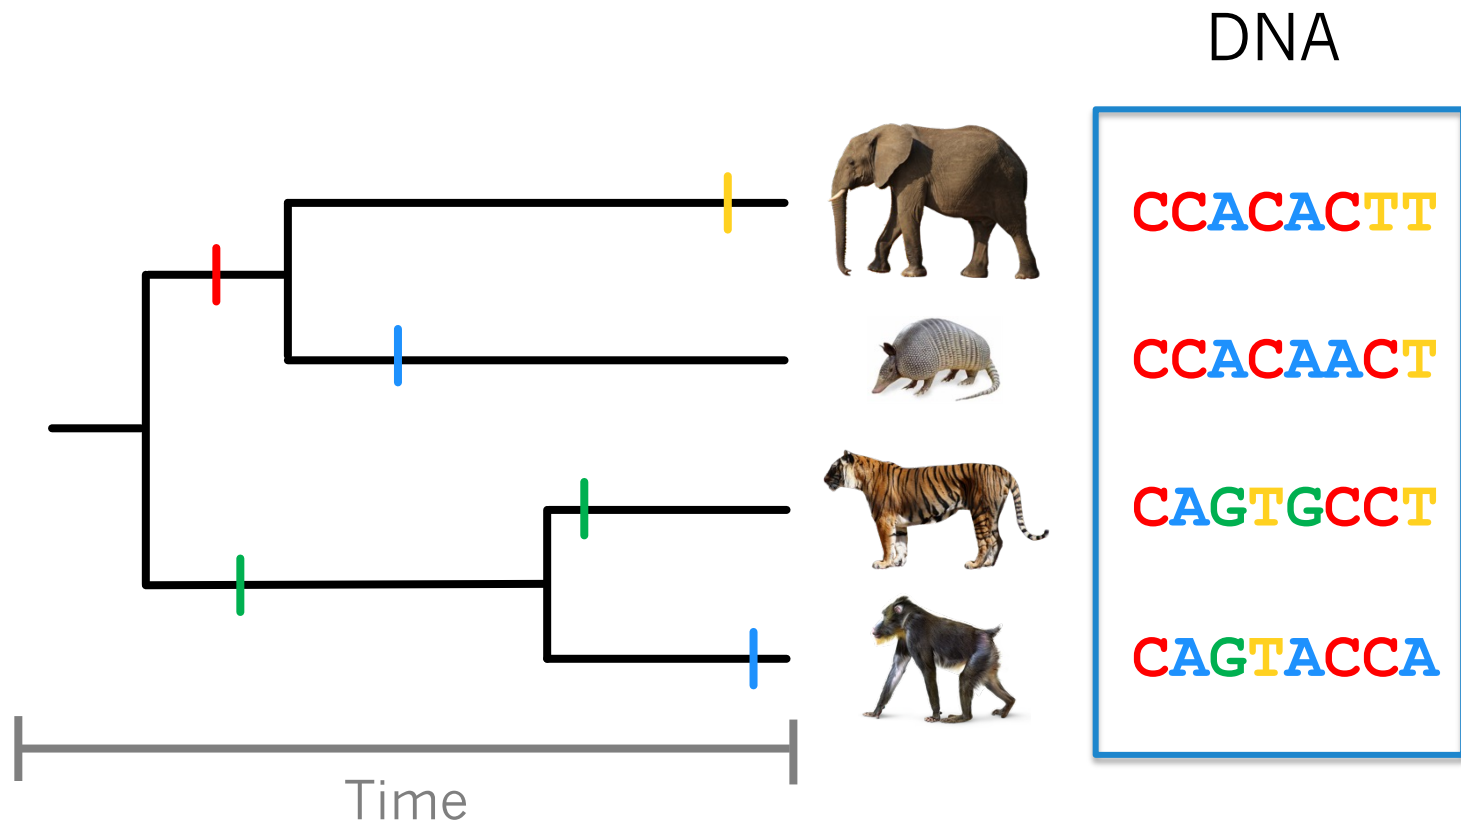

Statistical phylogenetics

How species related?

How old are they?

How did their traits evolve?

A likely history
(six mutations)

A less likely history
(twelve mutations)

Lecture 01 outline

Why bioinformatics?

Biol 4220 overview

Biol 4220 logistics

Introduction to Unix

Why bioinformatics?

Computers are essential to modern biological research

- \$1K human genome
- global biodiversity health
- human brain connectome
- tracking SARS-CoV-19
- identifying genetic diseases
- reconstructing tree of life

Why bioinformatics?

Different biological disciplines face similar computational challenges

Every year

- more data samples
- higher dimensional data
- methods grow more resource-intensive
- methods are more scalable
- methods are more interconnected
- need for reproducibility increases

More data samples

Genome cost fall by >50% every two years

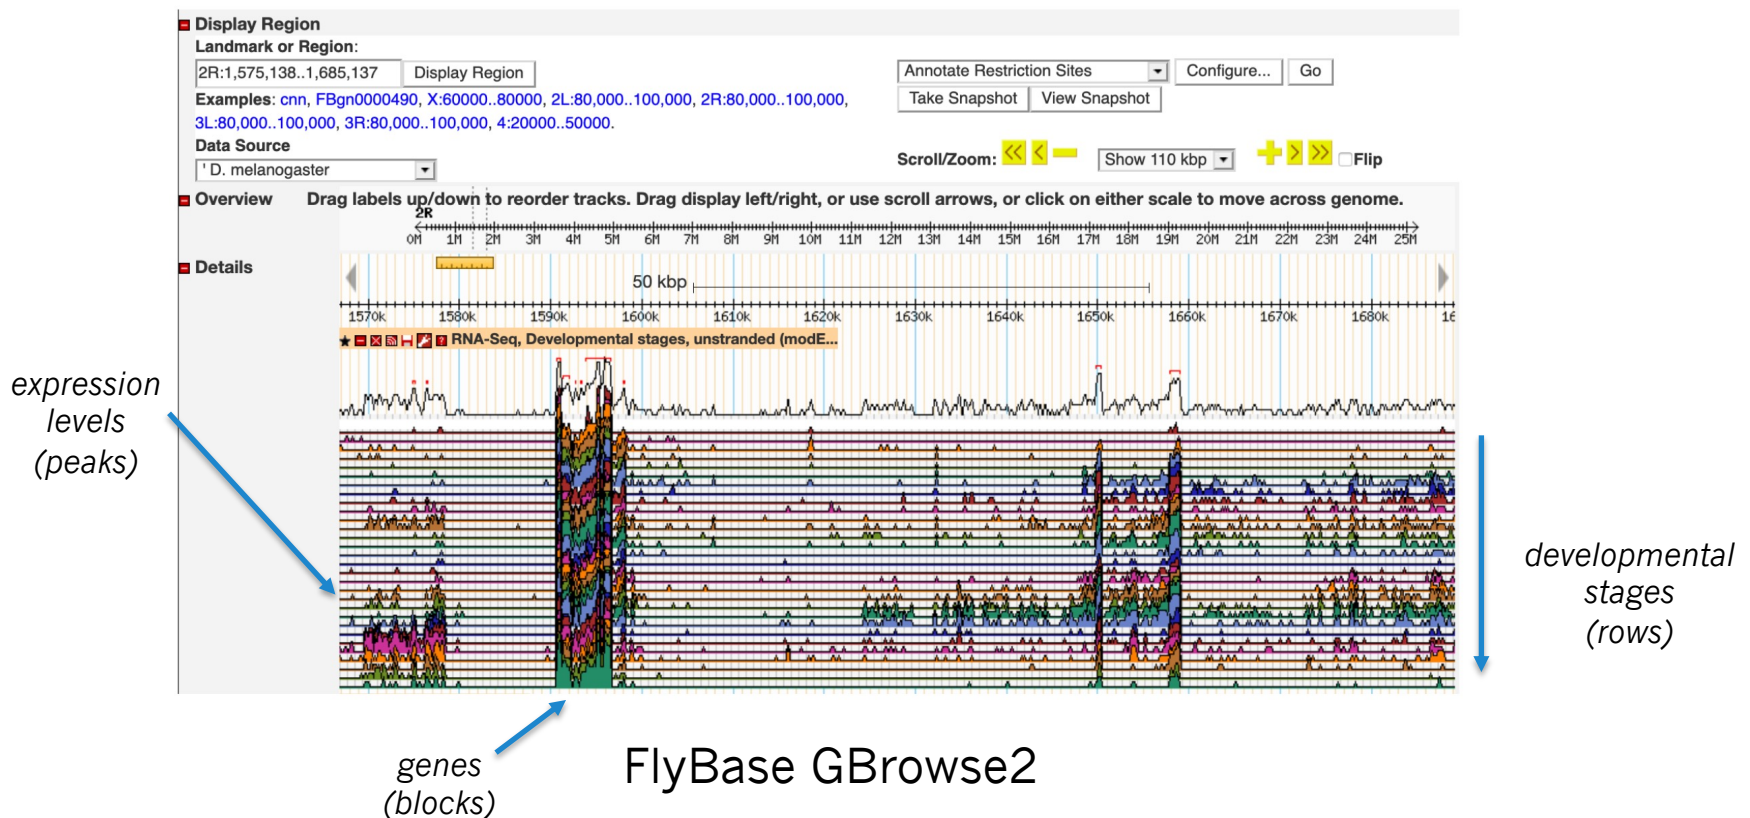

More data samples

1987 hard copy of
GenBank + EMBL

More data dimensions

Gene expression for fly
level x gene x developmental stage

More resource-intensive methods

Estimating the phylogeny for 6000+ mammal species took 120+ computer years

More scalable methods

25 million 35-bp reads per hour
3.2 Gbp in human genome

Bowtie

An ultrafast memory-efficient
short read aligner

JOHNS HOPKINS
UNIVERSITY

Bowtie is an ultrafast, memory-efficient short read aligner. It aligns short DNA sequences (reads) to the human genome at a rate of over 25 million 35-bp reads per hour. Bowtie indexes the genome with a Burrows-Wheeler index to keep its memory footprint small: typically about 2.2 GB for the human genome (2.9 GB for paired-end).

Bowtie: short-read alignment software

More interconnected methods

NCBI: 150k+ BLAST requests each weekday

provided by john.sullivan@nih.gov

Greater need for reproducibility

Computational methods allow exact reproduction of published results

from "Reproducible research in computational science"
in Peng (2011, Science)

What interests *you* in biological research?

You wrote:

- genetics and genomics
- cellular biology
- phylogenetics
- cancer biology
- gene expression
- personalized medicine
- immunology
- protein synthesis

Why are *you* interested in bioinformatics?

You wrote:

- curious about field
- learn new tools and techniques
- improve coding skills
- develop confidence
- learn about operating systems
- preparation for future career
- build an analysis pipeline
- tired of accidentally inhaling fruitflies

Biol 4220 topics

Computational skills

- Unix-based operating systems
- Python and shell scripts
- scientific computing libraries
- version control software
- bioinformatics pipeline design

Biological problems

- sequence processing
- molecular phylogenetics
- hypothesis testing

Course page

All course info is centralized here:

github.com/WUSTL-Biol4220/home

Contains links to:

- syllabus
- lectures
- labs
- course project
- GitHub Classroom

Labs

Each lab focuses on a new skill, but may require the use of previously learned skills

One lab is assigned per meeting (due after 1 week)

Completed alone or in groups, but each student must turn in their own work

Labs will be submitted using an online tool called GitHub Classrooms (introduced in Lab 01)

Course project

Design a pipeline to analyze genes

Pipelines will build upon lab skills

- download and align sequences
- summarize molecular variation
- build molecular phylogeny
- print and plot output
- add 2+ unique features

At the end of the semester, students will

- present their pipeline
- submit code, output, documentation

(more details later)

Exams

Exam 1 focuses on Weeks 1-7

Exam 2 focuses on Weeks 8-14

Problems closely follow problems from
lectures, labs, and reading

Dates are listed on schedule

Reading

Primary text

Allesina & Wilmes
ISBN: 9780691167299
~\$35

...other useful texts

Haddock & Dunn
ISBN: 0878933913
~\$60

Buffalo
ISBN: 1449367372
~\$35

Participation

Communicate with others!

Examples

- asking and/or answering questions
- working in groups
- helping other students
- visiting office hours
- discussing research problems

WUSTL Covid-19 policy

<https://covid19.wustl.edu/covid-19-plan-for-fall-2022/>

Summary

- must be vaccinated
- booster shots encouraged
- masking encouraged
- mild symptoms?
 - get tested + stay home
- no recorded lectures

Questions?

Operating systems (OS)

Operating systems coordinate user commands with computational resources & hardware

Examples:

- Windows
- Mac OS X (Unix-based)
- Linux (Unix-based)

Most scientific computing uses **Unix**-based systems; we'll be using the Linux distribution, **Ubuntu**

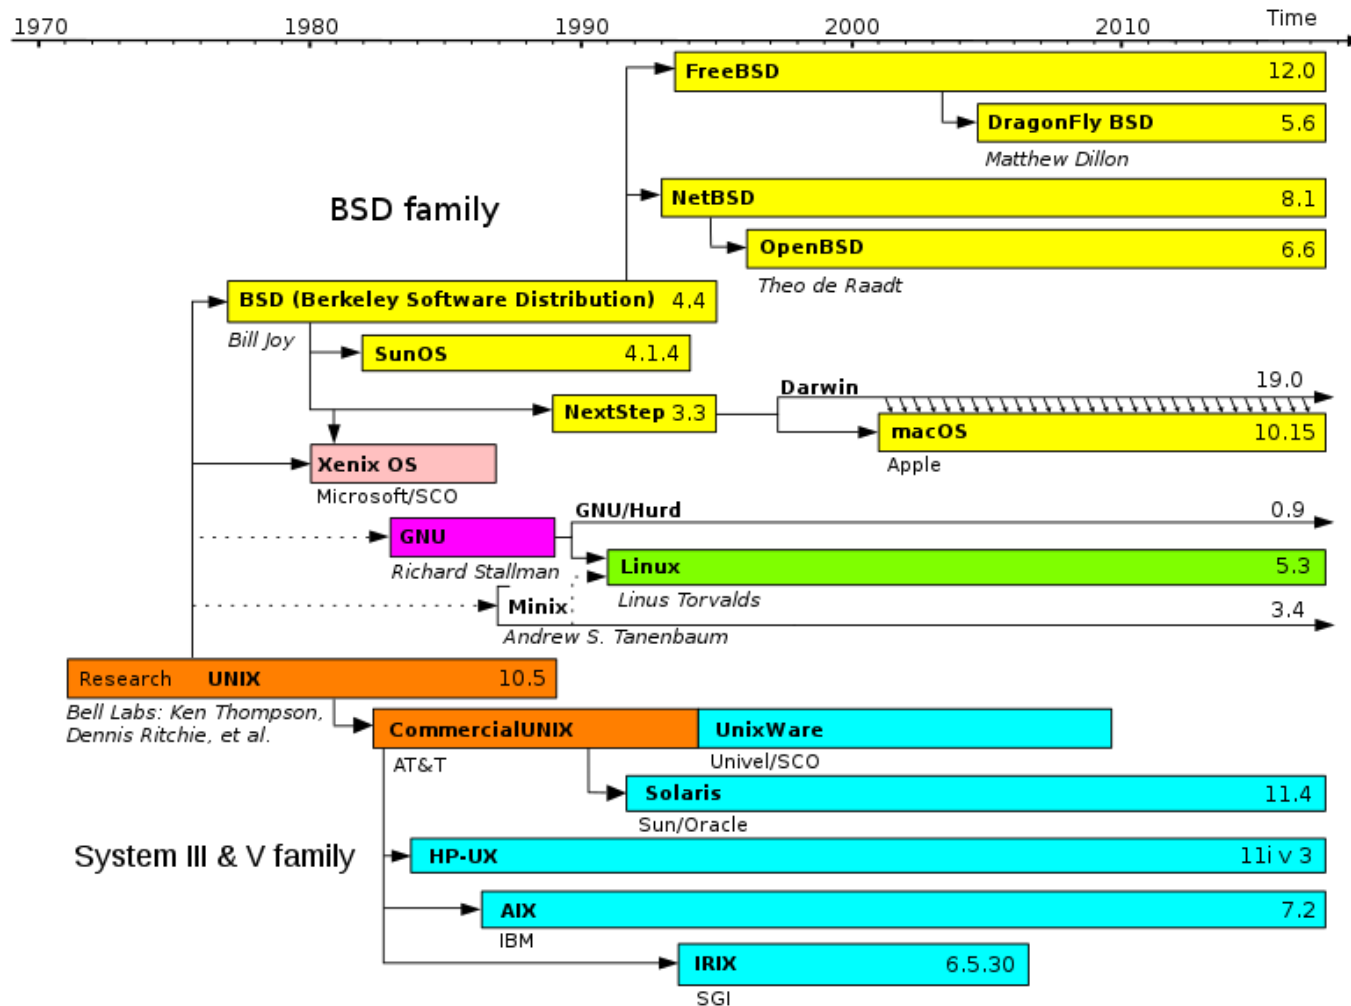

Operating systems (OS)

What do operating systems do?

They manage

- ***user interface*** for computer input/output
- ***scheduled tasks*** across multiple users/resources
- ***user interruptions*** of scheduled tasks
- ***memory use*** in efficient manner
- ***filesystem organization*** on hard drive
- ***user permissions*** for resource security
- ***network communication*** with other devices
- ***custom software*** to interact w/ OS and hardware

Unix family tree

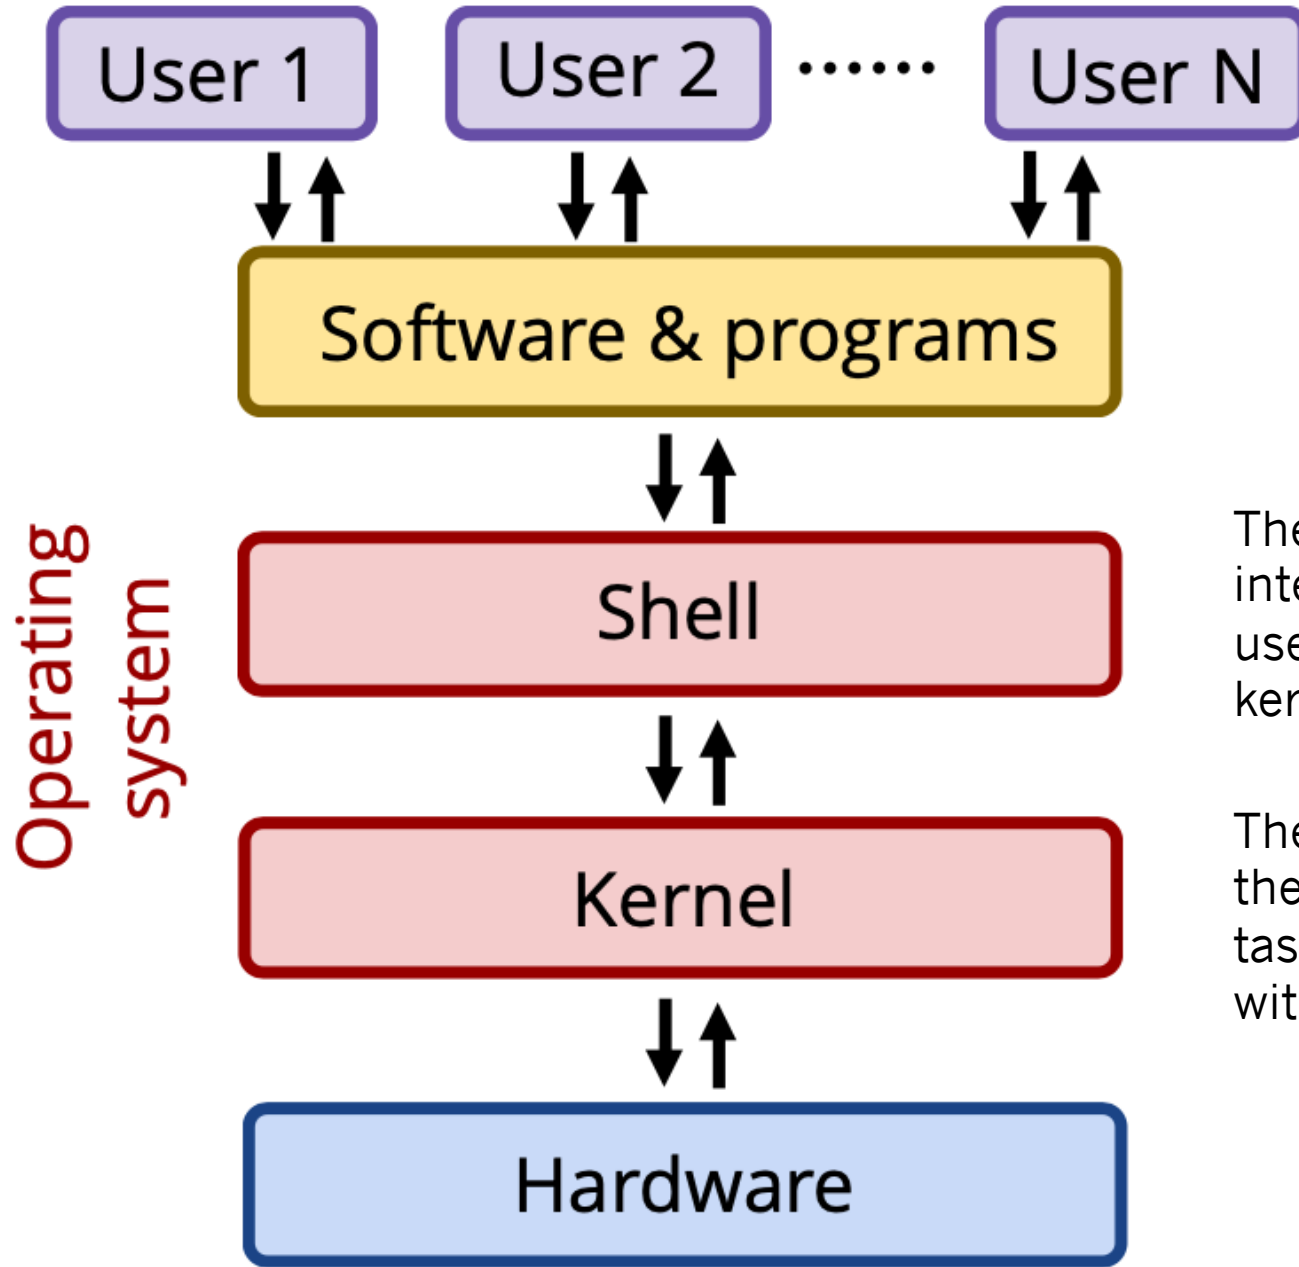

Ubuntu

We'll use Ubuntu 20.04 LTS

- Reliable testing + release cycles
- Excellent tutorials
<https://ubuntu.com/tutorials>
- Extremely active support community
<https://ubuntuforums.org>
- modified **Debian kernel** for stability
- popular **bash shell** by default

The ***shell*** is the interactive interface between the users, programs, and the kernel

The ***kernel*** is the core of the OS that controls all tasks and interfaces with the hardware

Kernel vs. shell

The **kernel** has control over all computer resources, including processors, memory, storage, devices, task management, etc.

The **shell** is a command line interface and scripting language that communicates user commands to the kernel for processing

```
> # connect to my workstation  
> ssh mlandis@128.252.89.47
```

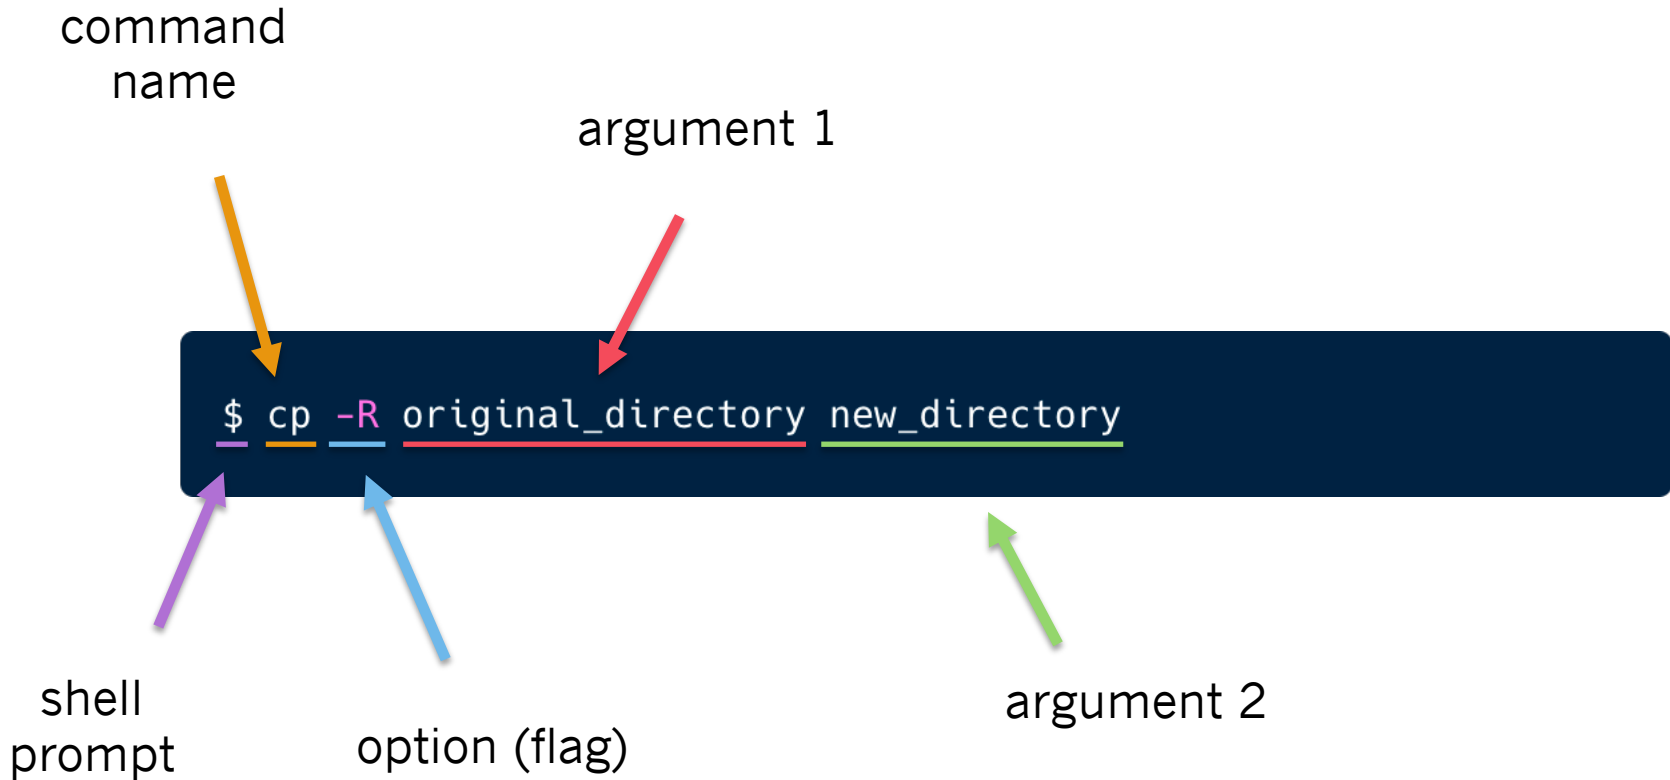

Example of Unix shell command

Command line

The ***command line*** accepts commands
provided by the user (you!)

Command string

A ***command*** is applied against an ***argument(s)*** and its behavior can be modified by ***option(s)***

Computers are predictable

- accept input as data
- process that data
- output processed data

Charles Babbage
“father of the computer”

“On two occasions, I have been asked [by members of Parliament], 'Pray, Mr. Babbage, **if you put into the machine *wrong* figures, will the right *answers* come out?**' I am not able to rightly apprehend the kind of confusion of ideas that could provoke such a question.”

Overview for Lab 01
