Lecture 01 Intro to practical bioinformatics

Practical Bioinformatics

Biol 4220 @ WUSTL

Course: Practical Bioinformatics (BIOL 4220)

Instructor: Michael Landis

Email: michael.landis@wustl.edu

Practical bioinformatics

Practice foundational computing skills for everyday biological research

We all have different backgrounds, research interests, goals, etc.

Practical bioinformatics

Broad goals:

- Develop confidence using computers
- Translate research ideas into code
- Solve problems independently
- Communicate in technical terms
- Stay healthy

Practical bioinformatics

Specific skills we'll develop:

- Write and debug programs
- Build your own analysis pipeline
- Test hypotheses with pipelines
- Make reproducible research
- Communicate research findings

Course page

All course information is centralized here:

github.com/WUSTL-Biol4220/home

Contains links to:

- syllabus
- lectures
- labs
- course project
- GitHub Classroom

Class info

```
Lecture + Lab

Mon + Wed, 8:30am – 12:00pm

Life Science 117 (computer lab)
```

Office hours
Thu, 2:00pm – 4:00pm
Rebstock 210 (by appointment)

Statistical phylogenetics

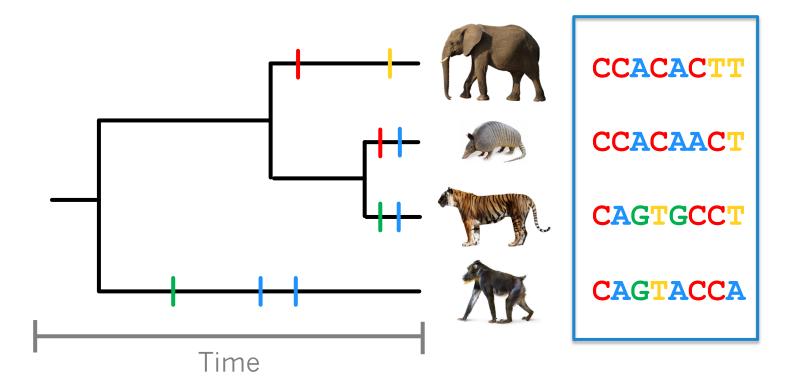

How species related? How old are they? How did their traits evolve?

DNA

A likely history (six mutations)

DNA

A less likely history (nine mutations)

Lecture 01 outline

Why bioinformatics?
Biol 4220 overview
Biol 4220 logistics
Introduction to Unix

Why bioinformatics?

Computers are essential to modern biological research

- sequencing the \$1K human genome
- assessing global biodiversity health
- mapping human brain connectome
- tracking SARS-CoV-19
- identifying genetic diseases
- reconstructing tree of life

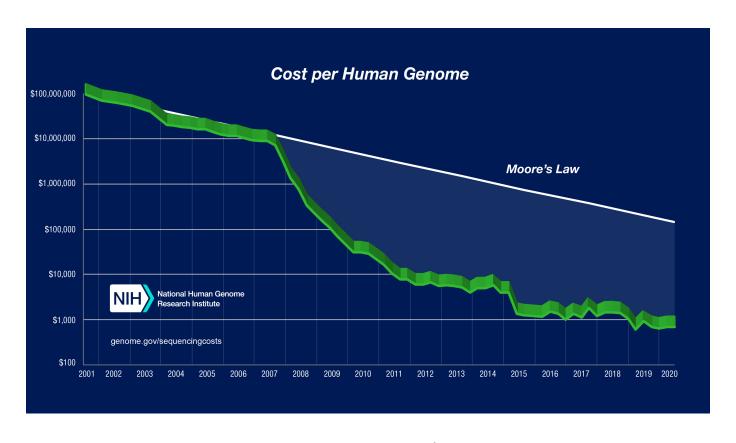

Why bioinformatics?

Different biological disciplines face similar computational challenges

Every year

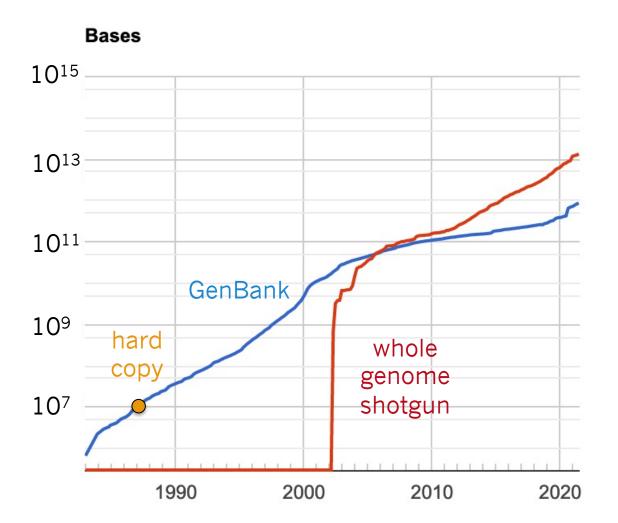

- more samples in data
- higher dimensions in data
- methods are more resource-intensive
- methods are more scalable
- methods are more interconnected
- need for reproducibility increases

More data samples

Genome cost fall by >50% every two years

More data samples

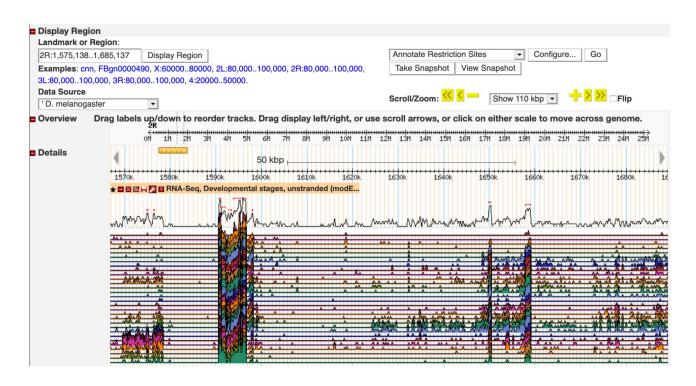

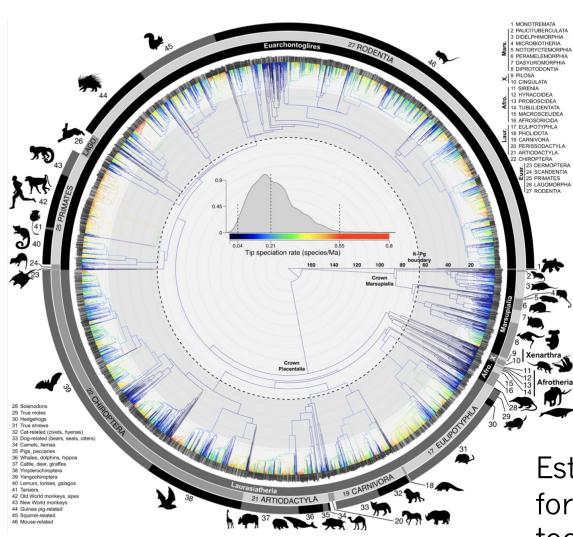

1987 hard copy of GenBank + EMBL

More data dimensions

Gene expression for fly level x gene x developmental stage

FlyBase GBrowse2

More resource-intensive methods

Estimating the phylogeny for 6000+ mammal species took 120+ computer years

More scalable methods

25 million 35-bp reads per hour 3.2 Gbp in human genome

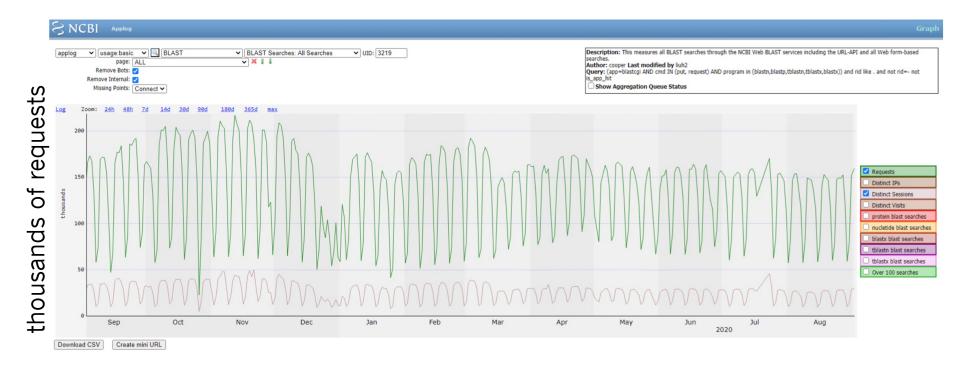

Bowtie is an ultrafast, memory-efficient short read aligner. It aligns short DNA sequences (reads) to the human genome at a rate of over 25 million 35-bp reads per hour. Bowtie indexes the genome with a Burrows-Wheeler index to keep its memory footprint small: typically about 2.2 GB for the human genome (2.9 GB for OSI certified paired-end).

Bowtie: short-read alignment software

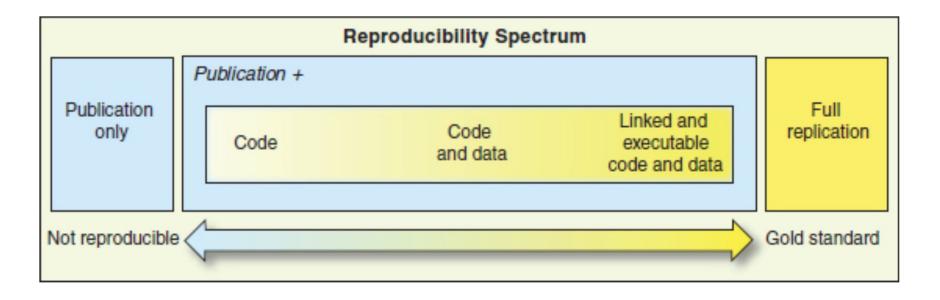

More interconnected methods

NCBI: 150k+ BLAST requests each weekday

Greater need for reproducibility

Computational methods allow exact reproduction of published results

from "Reproducible research in computational science" in Peng (2011, Science)

What interests *you* in biological research?

You wrote:

- genetics and genomics
- cellular biology
- epigenetics
- cancer biology
- mutation and evolution
- drug development
- immunology
- microbiome

Why are *you* interested in bioinformatics?

You wrote:

- computational problem solving
- connect biology + quantitative training
- learn new tools and techniques
- develop confidence
- appreciate history of field
- preparation for future career
- build an analysis pipeline
- pipetting hurts your thumb

Biol 4220 topics

Computational skills

- Unix-based operating systems
- Python and shell scripts
- scientific computing libraries
- version control software
- bioinformatics pipeline design

Biological problems

- sequence processing
- molecular phylogenetics
- hypothesis testing

Labs

Each lab focuses on a new skill, but may require the use of previously learned skills

One lab is assigned per meeting (due after 1 week)

Completed alone or in groups, but each student must turn in their own work

Labs will be submitted using an online tool called GitHub Classrooms (introduced in Lab 1a)

Course project

Design a pipeline to analyze genes

Pipelines will build upon lab skills

- download and align sequences
- summarize molecular variation
- build molecular phylogeny
- print and plot output
- add 2+ unique features

At the end of the semester, students will

- present their pipeline
- submit code, output, documentation

(more details later)

Exams

Exam 1 focuses on Weeks 1-7 Exam 2 focuses on Weeks 8-14

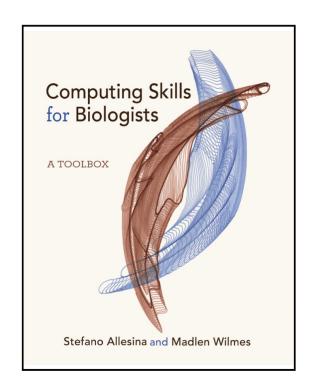

Problems closely follow problems from lectures, labs, and reading

Dates are listed on schedule

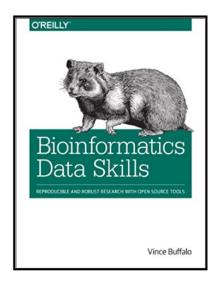

Reading

Primary text

...other useful texts

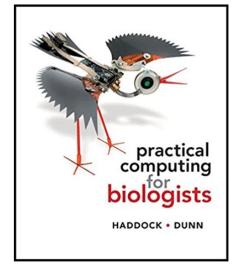

Allesina & Wilmes ISBN: 9780691167299 ~\$35

Haddock & Dunn ISBN: 0878933913 ~\$60

Buffalo ISBN: 1449367372 ~\$35

Participation

Communicate with others!

Examples

- asking and/or answering questions
- working in groups
- helping other students
- visiting office hours
- discussing research problems

Questions?

Operating systems (OS)

Operating systems coordinate user commands with computational resources & hardware

Examples:

- Windows
- Mac OS X (Unix-based)
- Linux (Unix-based)

Most scientific computing uses *Unix*-based systems; we'll be using the Linux distribution, *Ubuntu*

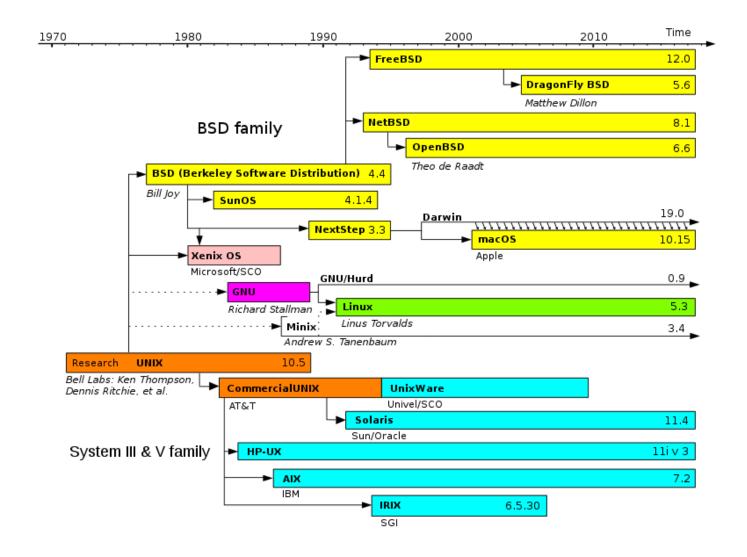

Operating systems (OS)

What do operating systems do?

They manage

- user interface for computer input/output
- scheduled tasks across multiple users/resources
- user interruptions of scheduled tasks
- memory use in efficient manner
- filesystem organization on hard drive
- user permissions for resource security
- network communication with other devices
- custom software to interact w/ OS and hardware

Unix family tree

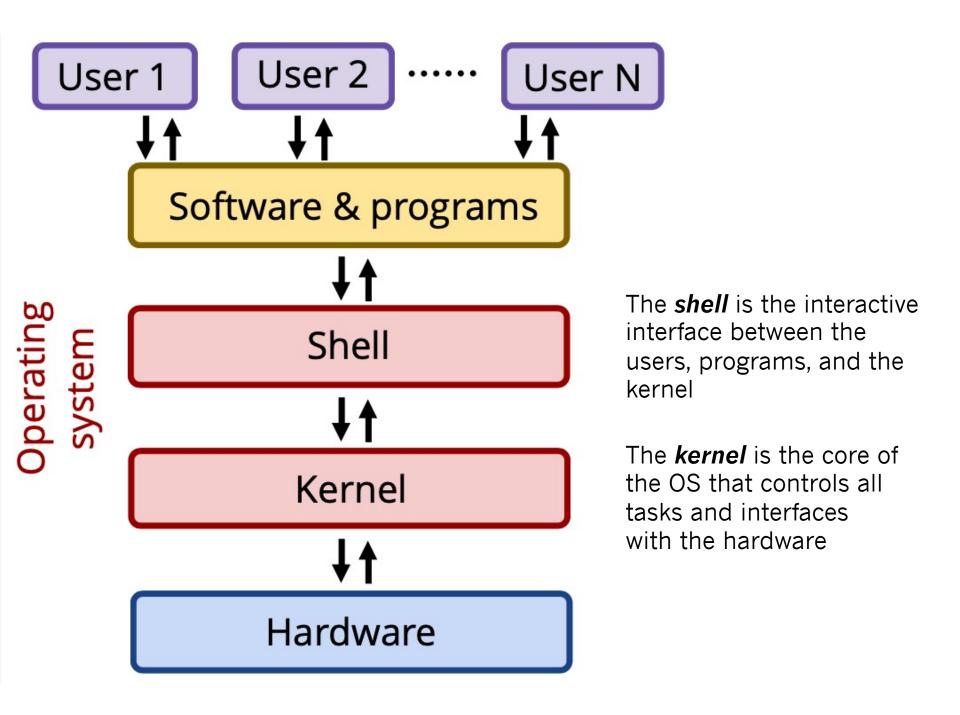

Ubuntu

We'll use Ubuntu 20.04 LTS

- Reliable testing + release cycles
- Excellent tutorials https://ubuntu.com/tutorials
- Extremely active support community https://ubuntuforums.org
- modified **Debian kernel** for stability
- popular **bash shell** by default

Kernel vs. shell

The **kernel** has control over all computer resources, including processors, memory, storage, devices, task management, etc.

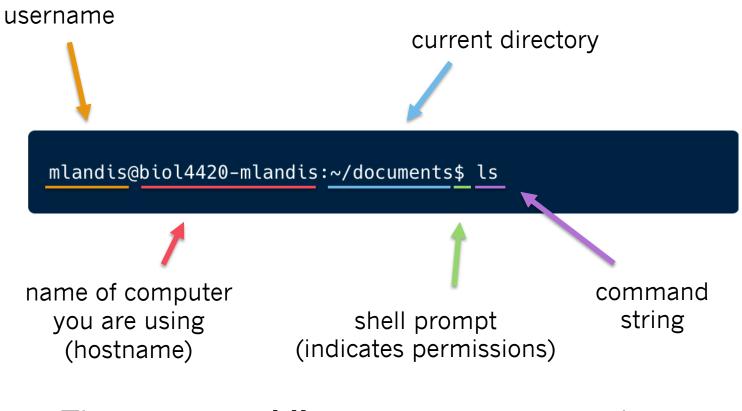

The **shell** is a command line interface and scripting language that communicates user commands to the kernel for processing

```
> # connect to my workstation
```

> ssh mlandis@128.252.89.47

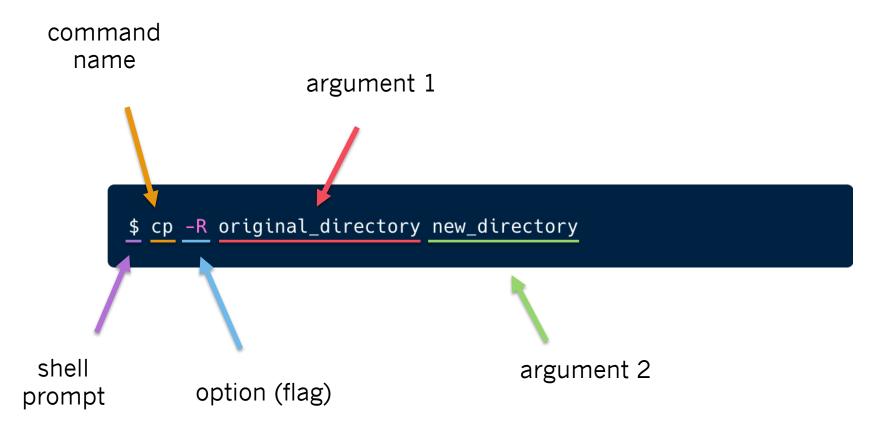

Example of Unix shell command

Command line

The **command line** accepts commands provided by the user (you!)

Command string

A **command** is applied against an **argument(s)** and its behavior can be modified by **option(s)**

Computers are predictable

- accept input as data
- process that data
- output processed data

"On two occasions, I have been asked [by members of Parliament], 'Pray, Mr. Babbage, if you put into the machine wrong figures, will the right answers come out?' I am not able to rightly apprehend the kind of confusion of ideas that could provoke such a question."

Charles Babbage "father of the computer"

Overview for Lab 01
